Climate Change: Policy and Mitigation

The Challenge
Climate change is a global problem that will require global cooperation to address. The objective of the United Nations Framework Convention on Climate Change (UNFCCC), which virtually all nations, including the U.S., have ratified, is to stabilize greenhouse gas (GHG) concentrations at a level that will not cause “dangerous anthropogenic (human-induced) interference with the climate system.” Due to the persistence of some GHGs in the atmosphere, significant emissions reductions must be achieved in coming decades to meet the UNFCCC objective. In 2018, the Intergovernmental Panel on Climate Change (IPCC) published the Special Report on Global Warming of 1.5°C. The report details the impacts of a 1.5°C temperature rise and proposes mitigation strategies to remain below the 1.5°C target. It will require lowering global carbon dioxide (CO$_2$) emissions in 2030 by 45% compared to 2010 and will require net zero emissions around 2050. Current national targets under the Paris Agreement would lead to 52–58 gigatons (Gt) CO$_2$-equivalents (CO$_2$e) per year by 2030 -- not enough to meet the 1.5°C target. In 2018, U.S. GHG emissions were 6.7 GtCO$_2$e.

General Policies

Market-Based Instruments
- Market-based approaches include carbon taxes, subsidies, and cap-and-trade programs. In a tradable carbon permit system, permits equal to an allowed level of emissions are distributed or auctioned. Parties with emissions below their allowance are able to sell their excess permits to other parties that have exceeded their emissions allowance.
- Market-based instruments are recognized for their potential to reduce emissions by allowing for flexibility and ingenuity in the private sector.

Regulatory Instruments
- Regulatory approaches include non-tradable permits, technology and emissions standards, product bans, and government investment. In 2007, the U.S. Supreme Court ruled that CO$_2$ and other GHG emissions meet the Clean Air Act’s definition of air pollutants, which are regulated by the U.S. Environmental Protection Agency (EPA). After several appeals, the U.S. Court of Appeals upheld the ruling in 2012.
- In the U.S., the Safer Affordable Fuel-Efficient (SAFE) vehicles rule, administered by NHTSA, was implemented in 2020. In comparison to the 2012 Corporate Average Fuel Economy (CAFE) standards, the SAFE rule has lower efficiency improvement targets of 1.5% per year and will result in 867-923 million metric tons more CO$_2$ emissions compared to CAFE standards.

Voluntary Agreements
- Voluntary agreements are generally made between a government agency and one or more private parties to “achieve environmental objectives or to improve environmental performance beyond compliance.” EPA partners with the public and private sectors to oversee a variety of voluntary programs aimed at reducing GHG emissions, increasing clean energy adoption, and adapting to climate change.

The Kyoto Protocol
- The Kyoto Protocol came into force on February 16, 2005, and established mandatory, enforceable targets for GHG emissions. Initial emissions reductions for participating countries ranged from −8% to +10% of 1990 levels, while the overall reduction goal was 5% below the 1990 level from 2008 to 2012. When the first commitment period ended in 2012, the Protocol was amended for a second commitment period; the new overall reduction goal would be 18% below 1990 levels by 2020.

The Paris Agreement
- In December of 2015, all Parties of the UNFCCC reached a climate change mitigation and adaptation agreement, called The Paris Agreement, in order to keep global temperatures below a 2°C increase above pre-industrial temperatures.
- The Paris Agreement entered into force on November 4, 2016. As of June 2020, The Paris Agreement had 197 signatories of which 189 parties accounting for at least 55% of total global emissions have ratified the agreement. In June 2017, President Trump announced that the U.S. would withdraw from the Paris Agreement. The withdrawal is scheduled to take place on November 4, 2020.

Government Action in the U.S.

Federal Policy
- According to the U.S. Senate, “...Congress should enact a comprehensive and effective national program of mandatory, market-based limits and incentives on emissions of greenhouse gases that slow, stop, and reverse the growth of such emissions at a rate and in a manner that will not significantly harm the United States economy and will encourage comparable action by other nations.”

In 2015, the proposed Clean Power Plan set a national limit for CO₂ emissions from power plants. In early 2016, the plan was stayed by the Supreme Court due to several lawsuits against it. In October 2017, the EPA proposed to repeal the Clean Power Plan. The repeal was finalized in 2019 and was replaced by the Affordable Clean Energy Rule.

Due to the Consolidated Appropriations Act of 2008, large emitters of GHGs in the U.S. must report emissions to the EPA.

In 2019, a Green New Deal resolution was introduced in the U.S. House. It proposes a 10-year mobilization effort to focus on goals such as net-zero GHG emissions, economic security, infrastructure investment, clean air and water, and promoting justice and equality.

State Policy

Climate change action plans have been enacted by 34 states and D.C.

23 states and D.C. have GHG emission reduction targets. For example, California is targeting emissions 40% below 1990 levels by 2030 and economy-wide carbon-neutrality by 2045.

29 states, D.C., and three U.S. territories have Renewable Portfolio Standards, which specify the percentage of electricity to be generated from renewable sources by a certain date. Three states have Clean Energy Standards, which specify the percentage of electricity to be generated from low-to-no carbon sources and can include renewables, nuclear, and advanced fossil fuel plants with carbon capture and sequestration. 25 governors have joined the US Climate Alliance, to uphold the GHG reductions outlined in the Paris Agreement. The alliance represents 55% of the U.S. population and more economic activity than all other Paris signatories other than the U.S. and China.

Mitigation Strategies

Stabilizing atmospheric CO₂ concentrations cannot be accomplished without changes in energy production and use. Effective mitigation cannot be achieved without individual agencies working collectively towards reduction goals. Stabilization wedges are one display of GHG reduction strategies; each wedge represents 1 billion tons of carbon avoided per year over 50 years.

Energy Savings: Many energy efficiency efforts require an initial capital investment, but the payback period is often only a few years. In 2016, the Minneapolis Clean Energy Partnership planned to retrofit 75% of Minneapolis homes for efficiency and allocated resources to buy down the cost of energy audits and provide no-interest financing for energy efficiency upgrades.

Fuel Switching: Switching power plants and vehicles to less carbon-intensive fuels can achieve emission reductions quickly. For instance, switching from an average coal plant to a natural gas combined cycle plant can reduce CO₂ emissions by approximately 50%.

Capturing and Storing Emissions: CO₂ can be captured from large point sources both pre- and post-combustion of fossil fuels. Once CO₂ is separated, it can be stored underground depending on the geology of a site. Currently, CO₂ is used in enhanced oil recovery (EOR), but long-term storage technologies remain expensive. Alternatively, existing CO₂ can be removed from the atmosphere through Negative Emissions Technologies and approaches such as direct air capture and sequestration, bioenergy with carbon capture and sequestration, and land management strategies.

Individual Action

There are many actions that individuals can take to reduce their GHG emissions; many involve energy conservation and also save money.

Choose a fuel-efficient or electric vehicle and keep your car well maintained, including properly inflated tires.

Decrease the amount you drive by using public transportation, riding a bike, walking, or telecommuting. For a 20-mile round trip commute, switching to public transit can prevent 4,800 lbs of CO₂ emissions per year.

Ask your electricity supplier about options for purchasing energy from renewable sources.

When purchasing appliances, look for the Energy Star label and choose the most energy efficient model.

Energy Star light bulbs use -90% less energy than a standard bulb, last 15 times longer, and save ~$55 in electricity costs over their lifetimes.

Space heating is the largest use of household energy (34%). Ensure that your house is properly sealed by reducing air leaks, installing the recommended level of insulation, and choosing Energy Star windows.
