U.S. Food System

Americans enjoy a diverse abundance of low-cost food, spending a mere 11.3% of disposable income on food. However, store prices do not reflect the external costs—economic, social, and environmental—that impact the sustainability of the food system. Considering the full life cycle of the U.S. food system illuminates the connection between consumption behaviors and production practices.

Patterns of Use

Agricultural Production

- Farmers account for 1% of the population. Over 60% of these farmers are above the age of 55.
- Large-scale family farms and industrial nonfamily farms account for only 5% of farms, but 63.8% of production (in $). Small-scale family farms represent 89% of U.S. farms, but only 17.8% of production.
- Just 14.5¢ of every dollar spent on food in 2021 went back to the farm; in 1975, it was 40¢.
- In 2018-2020, 41% of the hired agricultural labor force lacked authorization to work in the United States.
- From 1992 to 2012, total cropland decreased from 460 million acres to 392 million acres.
- Many parts of the U.S., including agricultural regions, are experiencing increasing groundwater depletion (withdrawal exceeds recharge rate).

Consumption Patterns

- In 2010, the U.S. food supply provided 4,000 calories per person per day. Accounting for waste, the average American consumed 2,501 calories per day in 2010, an increase of 22% from 1970.
- In 2021, 185 lbs of meat per person were available for consumption, up 11.6 lbs from 1969. Although red meat consumption declined 24% since the 1970s, chicken consumption has increased.
- 34% of grains grown are used to feed animals.
- 22.2 teaspoons of sweeteners are available per capita in the U.S. daily; the American Heart Association recommends limiting added sugars to 6 and 9 teaspoons daily for average females and males, respectively.
- Approximately 41% of U.S. adults and over 20% of 12-19 year olds are obese (BMI > 30).
- Diet plays a significant role in health. Diets lacking fruits and vegetables can increase risk of heart disease, certain cancers, and stroke—leading causes of U.S. deaths.
- The EPA estimates that 30%-40% of the current food supply was lost as waste, 50% more than in 1970. More food waste reaches landfills than any other material. This waste accounted for roughly 22% of the municipal solid waste stream in 2018 and represents a loss of $340 and around 350 pounds of food waste per person each year.
- One estimate suggests that 2% of total annual energy use in the U.S. is used to produce food that is later wasted.

Life Cycle Impacts

The energy used by a system is often a useful indicator of its sustainability. Food-related energy use accounts for over 12% of the national energy budget. Agriculture and the food system as a whole have developed a dependence on fossil energy; 13 units of (primarily) fossil energy are used for every unit of food energy produced. Food production of U.S. self-selected diets results in 4.7 kg CO₂e and 25.2 MJ fossil fuel energy demand per capita per day. Reliance on fossil fuel inputs makes the food system vulnerable to oil price fluctuations. Consolidation of farms, food processing operations, and distribution warehouses often increases distance between food sources and consumers. Consolidation in the food system is also concentrating management decisions into fewer hands. For example: Four firms control 85% of the beef packing market; 82% of soybean processing is controlled by four firms. The top four food retailers sold almost 35% of America’s food in 2019, compared to only 15% in 1990.

Solutions and Sustainable Alternatives

Eat Less Meat

Meat-based diets use more energy to produce than vegetarian diets, one study suggests twice as much. One serving of beef has more associated GHG emissions than 20 servings of vegetables. Current meat production also has significant environmental impacts on land use, water use, and water pollution. In an average diet, meat consumption accounts for 31% of the water scarcity footprint — the water use that accounts for regional scarcity. 20% of Americans cause half of the food-related GHG emissions; a diet shift away from meat could reduce this up to 73%.

Reduce Waste

Much of household food waste is due to spoilage. Prevent this by buying smaller amounts; planning meals and sticking to shopping lists; and freezing, canning, or preserving extra produce. Direct-to-consumer meals streamline the supply chain, reduce food waste and last-mile transportation, and have 25% lower GHG emissions than a store bought meal. Many safe foods are thrown out due to confusion about “sell-by” and “use-by” dates; for guidance, see the USDA. Whether washing dishes manually or in a dishwasher, save water and energy by practices such as not letting water run constantly, rinsing in cold water, only running dishwashers with full loads, and avoiding pre-rinsing dishes.

Use Less Refrigeration

Home refrigerator accounts for 13% of all energy consumed by our food system. Refrigerator efficiency more than doubled from 1972 to 1990, when the first set of efficiency standards took effect. Yet increases in size have largely offset this improvement. Today’s convenience foods rely heavily on refrigeration for preservation. Switching out old refrigerators with more efficient models (e.g., ENERGY STAR) can save energy and money. Also consider buying smaller quantities of fresh produce more frequently.

Eat Organic

Organic farms do not use chemicals that require large amounts of energy to produce, pollute soil and water, and cause human health impacts. U.S. sales of organic food in 2022 were $61.7 billion, 19.6% higher than in 2019; organic food now accounts for approximately 6% of all food sold in the U.S.

Eat Local

Transportation accounts for approximately 14% of the total energy used in the U.S. food system. There is significant room for improvement in how people acquire their food. Community Supported Agriculture and Farmers Markets are great ways to support your local food system.
