U.S. Food System

Americans enjoy a diverse abundance of low-cost food, spending a mere 8.6% of disposable income on food. However, store prices do not reflect the external costs—economic, social, and environmental—that impact the sustainability of the food system. Considering the full life cycle of the U.S. food system illuminates the connection between consumption behaviors and production practices.

Patterns of Use

Agricultural Production
- Farmers account for 1% of the population. Almost 28% of these farmers are between the ages of 55 and 64.
- Large-scale farms and industrial nonfarm families account for only 4.8% of farms, but 57.4% of production (in $). Small-scale family farms represent nearly 90% of U.S. farms, but only 21.5% of production.
- Just 14.36 of every dollar spent on food in 2019 went back to the farm; in 1975, it was 40.6.
- Between 2014 and 2016, 48% of the hired agricultural labor force lacked authorization to work in the United States.
- From 1992 to 2012, total cropland decreased from 460 million acres to 392 million acres.
- Many parts of the U.S., including agricultural regions, are experiencing increasing groundwater depletion (withdrawal exceeds recharge rate).
- From 1992 to 2012, total irrigated cropland decreased from 58 million acres to 40 million acres.
- In 2010, the U.S. food supply provided 4,000 calories (176,000 kilocalories) per person for an average diet.
- In 2000, 25% of corn, 61% of cotton, and 54% of soybeans planted were genetically engineered; by 2020, these percentages increased to 92%, 96%, and 94%, respectively.
- The UN’s Food and Agriculture Organization estimates 75 billion metric tons of soil are lost annually to erosion from fertile lands.
- Agriculture was responsible for 9.6% of total U.S. greenhouse gas (GHGs) emissions in 2019. Methane (CH₄), nitrous oxide (N₂O), and carbon dioxide (CO₂) are the main GHGs emitted by agricultural activities. Livestock and soil management are major contributors.

Consumption Patterns
- In 2010, the U.S. food supply provided 4,000 calories per person per day. Accounting for waste, the average American consumed 2,501 calories per day in 2010, an increase of 22% from 1970.
- In 2019, 185 pounds of meat per person were available for consumption, up 11 pounds from 1969. Although red meat consumption declined 24% since the 1970s, chicken consumption increased steadily.
- 30% of grains grown are used to feed animals.
- 21.5 teaspoons of sweeteners are available daily per capita in the U.S.; the American Heart Association recommends limiting added sugars to 6 and 9 teaspoons daily for average females and males, respectively.
- Approximately 41% of U.S. adults and over 20% of 12-19 year olds are obese (BMI > 30).
- Diet plays a significant role in health. Diet lacking fruits and vegetables can increase risk of heart disease, certain cancers, and stroke—leading causes of U.S. deaths.
- The EPA estimated that in 2010, 31% of the food supply was lost, 50% more than in 1970. In 2018, more food reached landfills than any other material.
- This waste accounts for roughly 22% of the municipal solid waste stream and represents a loss of $450 per person each year.
- One estimate suggests that 2% of total annual energy use in the U.S. is used to produce food that is later wasted.

Solutions and Sustainable Alternatives

Eat Less Meat

Meat-based diets use more energy to produce than vegetarian diets, one study suggests twice as much.16 One serving of beef has more associated GHG emissions than 20 servings of vegetables.26 Current meat production also has significant environmental impacts on land use, water use, and water pollution.28 In an average diet, meat consumption accounts for 31% of the water scarcity footprint—the water use that accounts for regional scarcity.27 20% of Americans cause half of the food-related GHG emissions; a diet shift away from meat could reduce this up to 73%.28

Reduce Waste

Much of household food waste is due to spoilage. Prevent this by buying smaller amounts; planning meals and sticking to shopping lists; and freezing, canning, or preserving extra produce.20 Direct-to-consumer meal streamlines the supply chain, reduce food waste and last-mile transportation, and have 25% lower GHG emissions than a store bought meal.44 Many safe foods are thrown out due to confusion about “sell-by” and “use-by” dates; for guidance, see the USDA.46 Whether washing dishes manually or in a dishwasher, save water and energy by practices such as not letting water run constantly, rinsing in cold water, only running dishwashers with full loads, and avoid pre-rinsing dishes.48

Use Less Refrigeration

Home refrigeration accounts for 13% of all energy consumed by our food system.47 Today’s convenience foods rely heavily on refrigeration for preservation. Consider a smaller, more efficient refrigerator and buying smaller quantities of fresh produce more frequently. Refrigerator efficiency more than doubled from 1977 to 1997, but increases in size have largely offset this improvement.49

Eat Organic

Organic farms do not use chemicals that require large amounts of energy to produce, pollute soil and water, and present human health impacts.49 Sales of organic food in 2020 were 12.8% higher than in 2019; organic food now accounts for approximately 6% of all food sold in the U.S.54

Eat Local

Transportation accounts for approximately 14% of the total energy used in the U.S. food system.45 There is significant room for improvement in how people acquire their food. Community Supported Agriculture and Farmers Markets are great ways to support your local food system.

Life Cycle Impacts

The energy used by a system is often a useful indicator of its sustainability. Food-related energy use accounts for over 12% of the national energy budget.29 Agriculture and the food system as a whole have developed a dependence on fossil fuel; 13 units of (primarily) fossil energy are used for every unit of food energy produced.30,31

- Food production of U.S. self-selected diets amounts to 4.7 kg CO₂e and 25.2 MJ fossil fuel energy demand per capita per day.32
- Reliance on fossil fuel inputs makes the food system increasingly vulnerable to oil price fluctuations.33
- Consolidation of farms, food processing operations, and distribution warehouses often increases distance between food sources and consumers.34
- Consolidation in the food system is also concentrating management decisions into fewer hands. For example:
  - Four firms control 8% of the beef packing market; 82% of soybean processing is controlled by four firms.35
  - The top four food retailers sold almost 35% of America’s food in 2019, compared to only 15% in 1990.36
